

# Software Engineering for Embedded Systems

Chapter 5

Renesas Electronics America Inc. Advanced Embedded Systems using the RX63N

Rev. 0.1

## **Topics**

- Need for a structured development process
- Overview
- Software development stages
- Software development lifecycle models

## Need for a structured development process

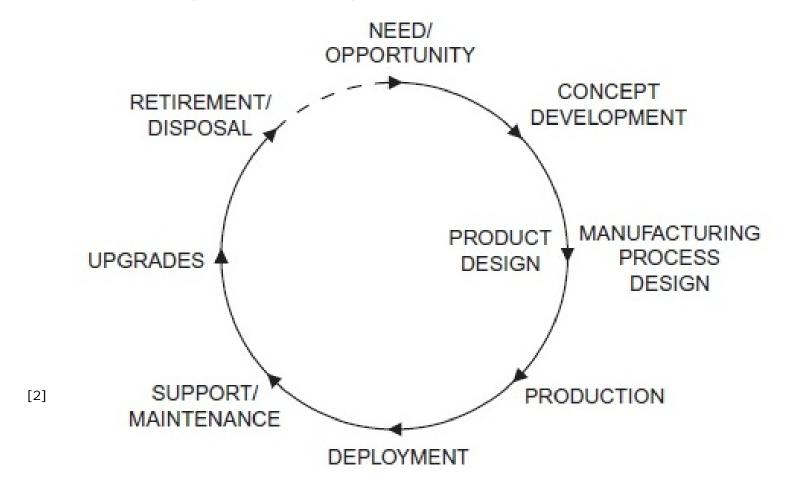

Consider following common software system occurrences:

- Unpredictability of software
- Buggy code
- Unexpected behavior of peripherals
- Incompetency of developer
- Budget constraints

We need a structured process to reduce risks involved in software development process

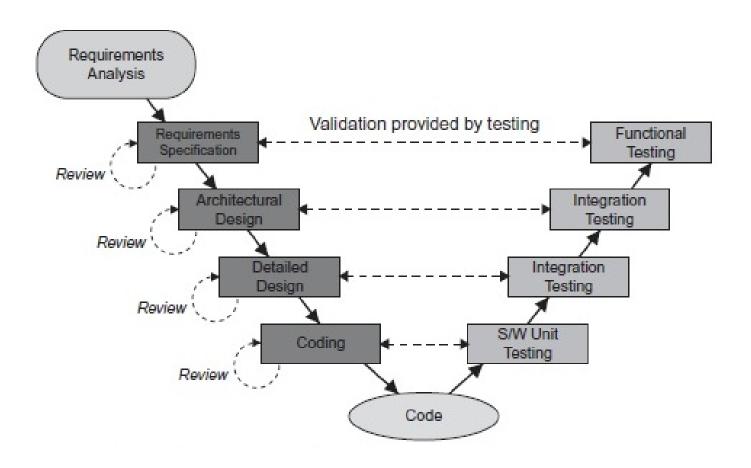

#### **Overview**

Following figure simply explains various stages of an embedded systems lifecycle

# **Example model**

The "V" model emphasizes on testing at each level of the software development process

## Software Developments stages

- Requirements
- Design before coding
- Peer review
- 4. System architecture and Design approach
- Detailed design
- Implementation
- 7. Software testing

## 1. Requirements

- They have to be written down so that every team member has clear idea of what is expected. Requirements can be expresses in text or graph.
- There are three types:
- Functional requirements: state the expected functionality of the system
- Non-functional requirements: describe system behavior like response time, energy efficiency
- 3. Constraints: define the limits on the system like cost

## 2. Design before coding

- All the parts of the system should be understood to know what parts are going to be complex to code
- It only saves time working on the code
- Graphical representations like flowchart make coding easier
- Coding too soon or before designing may not be the most efficient way of implementation

#### 3. Peer review

- Getting peer review helps in broadening the perspective on the project implementation
- It helps detect oversights and misconceptions or mistakes
- Also knowing that peer will be reviewing your software makes you careful and professional

# 4. System architecture and Design approach

- The system architecture defines what processor and peripherals will be used
- It should also divide the software into major parts
- The documentation should include which processing is timecritical and safety-critical and how the system is designed to take care of it

## 5. Detailed Design

- It involves defining and designing the subsystems of the architecture
- The software can be divided into functions and ISRs
- It is better if the software design is defined in steps of algorithm or flowchart of every function
- Designing should take into consideration all the requirements and constraints

## 6. Implementation

- The detailed design should be actually coded and programmed into the processor
- C is the most dominant programming language for embedded systems
- The code should be simple, generic and clear
- The code should follow the team or company's coding standards

## 7. Software testing

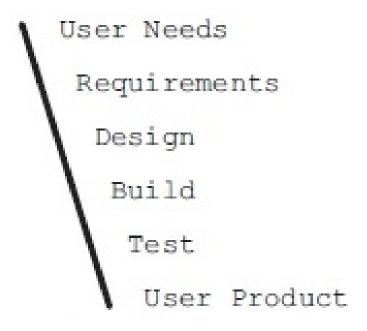

- It is impossible to create error-free code, for a system that will handle all possible input conditions in single try.
- Software testing verifies the completeness of the system and identifies the software's weaknesses.
- Black box testing tests the functionality of the software. How the software implements it is unimportant to the test.
- White box testing relies on the knowledge of the software. The tester makes sure he/she goes through every conditions and functions of the software and check for desired results.
- Bugs occurred in the past are repeatedly checked. This is called regression testing.

## Software Development Lifecycle Models

- The model which lists the steps in the lifecycle is the waterfall model. It is an idealized model
- The models like iterative process, spiral process, agile development and prototyping are actually used in software development

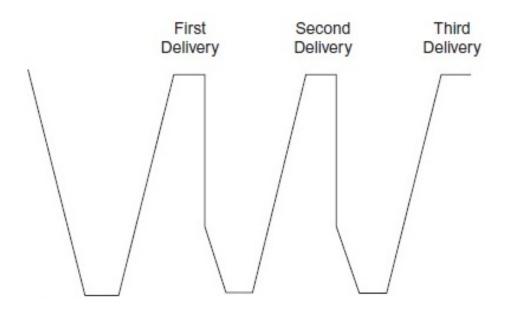

#### Waterfall model

- It is an ideal model and there is no reviewing process involved between the stages
- The model is appropriate to follow when the problem is well understood and there is little risk

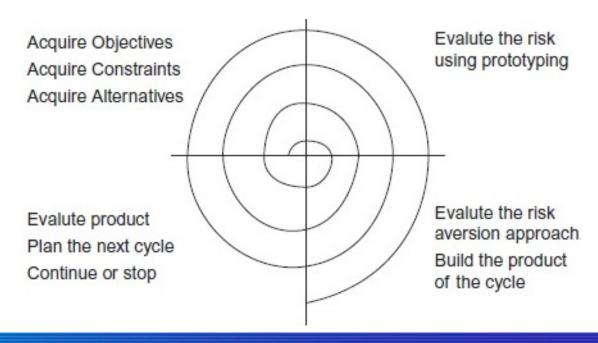

#### Iterative process

- This process is used when the customer wants the product to be developed based on customer's feedback
- This process is successful when the development time is short

#### Spiral process

- This is a process which involves constant development over previous cycle, often used in high risk projects like research in new technology
- Its stages are requirements, designing a prototype, building the product and evaluation of the product which leads to further development

## **Agile Development process**

- The most common agile development methods are scrum, extreme programming and lean development
- These methods seek to deliver the product to the customer as early as possible
- With scrum, the development is divided into 'sprints'. Each sprint has specific goals to be achieved. The scrum master solves any problems faced by a team member and allows speedy completion of the sprint

## **Prototyping**

- In this process, the developer presents a prototype of the product to the customer
- This works best when performed as iterative or spiral process

#### There are two basic types:

- Throw away prototype: Developer uses demonstration tool or language to build prototype and throws away the prototype to build the actual product with real programming language
- Evolutionary prototype: Developer uses code from prototype to build the actual product

#### Conclusion

The software development stages are:

- Requirements
- Design before coding
- Peer review
- 4. System architecture and design approach
- Detailed design
- 6. Implementation
- 7. Software testing

The various software development models that can be used are waterfall, iterative process, spiral process, agile development and prototyping.
