slides11-1

Chapter 11

Numerical Algorithms

Numerical Algorithms

In textbook do:

- Matrix multiplication
- Solving a system of linear equations

Matrices — A Review

An $n \times m$ matrix

Matrix Addition

Involves adding corresponding elements of each matrix to form the result matrix.

Given the elements of **A** as $a_{i,j}$ and the elements of **B** as $b_{i,j}$, each element of **C** is computed as

 $c_{i,j} = a_{i,j} + b_{i,j}$ (0 i < n, 0 j < m)

Matrix Multiplication

Multiplication of two matrices, **A** and **B**, produces the matrix **C** whose elements, $c_{i,j}$ (0 i < n, 0 j < m), are computed as follows:

$$c_{i,j} = \frac{l-1}{k=0} a_{i,k} b_{k,j}$$

where **A** is an $n \times I$ matrix and **B** is an $I \times m$ matrix.

$\begin{array}{l} \mbox{Matrix-Vector Multiplication} \\ \mbox{$\mathbf{c}=\mathbf{A}\times\mathbf{b}$} \end{array}$

Matrix-vector multiplication follows directly from the definition of matrix-matrix multiplication by making **B** an $n \times 1$ matrix (vector). Result an $n \times 1$ matrix (vector).

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Relationship of Matrices to Linear Equations

A system of linear equations can be written in matrix form:

Ax = b

Matrix A holds the a constants

x is a vector of the unknowns

b is a vector of the *b* constants.

Implementing Matrix Multiplication

Sequential Code

Assume throughout that the matrices are square ($n \times n$ matrices).

The sequential code to compute $\mathbf{A} \times \mathbf{B}$ could simply be

```
for (i = 0; i < n; i++)
for (j = 0; j < n; j++) {
    c[i][j] = 0;
    for (k = 0; k < n; k++)
        c[i][j] = c[i][j] + a[i][k] * b[k][j];
}</pre>
```

This algorithm requires n^3 multiplications and n^3 additions, leading to a sequential time complexity of (n^3) . Very easy to parallelize.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Parallel Code

With n processors (and $n \times n$ matrices), can obtain:

- Time complexity of O(n²) with n processors Each instance of inner loop independent and can be done by a separate processor
- Time complexity of O(n) with n² processors One element of A and B assigned to each processor. Cost optimal since $O(n^3) = n \times O(n^2) = n^2 \times O(n)$].
- Time complexity of O(log n) with n³ processors
 By parallelizing the inner loop. Not cost-optimal since O(n³) n³×O(log n)).

O(log n) lower bound for parallel matrix multiplication.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Partitioning into Submatrices

Suppose matrix divided into s^2 submatrices. Each submatrix has $n/s \times n/s$ elements. Using notation $\mathbb{A}_{p,q}$ as submatrix in submatrix row p and submatrix column q:

The line

$$C_{p,q} = C_{p,q} + A_{p,r} * B_{r,q};$$

means multiply submatrix $A_{p,r}$ and $B_{r,q}$ using matrix multiplication and add to submatrix $C_{p,q}$ using matrix addition. Known as *block matrix multiplication*.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved.

Block Matrix Multiplication

(a) Matrices

(b) Multiplying $A_{0,0} \times$ to obtain $C_{0,0}$

$$\begin{bmatrix} a_{0,0} & a_{0,1} & a_{1,2} & a_{1,3} \\ a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} \\ a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} \end{bmatrix} \times \begin{bmatrix} b_{0,0} & b_{0,1} & b_{0,2} & b_{0,3} \\ b_{1,0} & b_{1,1} & b_{1,2} & b_{1,3} \\ b_{2,0} & b_{2,1} & b_{2,2} & b_{2,3} \\ b_{3,0} & b_{3,1} & b_{3,2} & b_{3,3} \end{bmatrix}$$
$$B_{0,0} = \begin{bmatrix} a_{0,0} & a_{0,1} \\ a_{1,0} & a_{1,1} \end{bmatrix} \times \begin{bmatrix} b_{0,0} & b_{0,1} \\ b_{1,0} & b_{1,1} \end{bmatrix} + \begin{bmatrix} a_{0,2} & a_{0,3} \\ a_{1,2} & a_{1,3} \end{bmatrix} \times \begin{bmatrix} b_{2,0} & b_{2,1} \\ b_{3,0} & b_{3,1} \end{bmatrix}$$
$$= \begin{bmatrix} a_{0,0}b_{0,0} + a_{0,1}b_{1,0} & a_{0,0}b_{0,1} + a_{0,1}b_{1,1} \\ a_{1,0}b_{0,0} + a_{1,1}b_{1,0} & a_{1,0}b_{0,1} + a_{1,1}b_{1,1} \end{bmatrix} + \begin{bmatrix} a_{0,2}b_{2,0} + a_{0,3}b_{3,0} & a_{0,2}b_{2,1} + a_{0,3}b_{3,1} \\ a_{1,2}b_{2,0} + a_{1,3}b_{3,0} & a_{1,2}b_{2,1} + a_{1,3}b_{3,1} \end{bmatrix}$$
$$= \begin{bmatrix} a_{0,0}b_{0,0} + a_{0,1}b_{1,0} + a_{0,2}b_{2,0} + a_{0,3}b_{3,0} & a_{0,0}b_{0,1} + a_{0,1}b_{1,1} + a_{0,2}b_{2,1} + a_{0,3}b_{3,1} \\ a_{1,0}b_{0,0} + a_{1,1}b_{1,0} + a_{1,2}b_{2,0} + a_{1,3}b_{3,0} & a_{1,0}b_{0,1} + a_{1,1}b_{1,1} + a_{1,2}b_{2,1} + a_{0,3}b_{3,1} \\ a_{1,0}b_{0,0} + a_{1,1}b_{1,0} + a_{1,2}b_{2,0} + a_{1,3}b_{3,0} & a_{1,0}b_{0,1} + a_{1,1}b_{1,1} + a_{1,2}b_{2,1} + a_{1,3}b_{3,1} \end{bmatrix}$$

Direct Implementation

One processor to compute each element of $\mathbf{C} - n^2$ processors would be needed. One row of elements of **A** and one column of elements of **B** needed. Some of same elements sent to more than one processor. Can use submatrices.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Performance Improvement

Using tree construction n numbers can be added in log n steps using n processors:

Recursive Implementation

Apply same algorithm on each submatrix recursivly.

Excellent algorithm for a shared memory systems because of locality of operations.

Recursive Algorithm

```
mat_mult(A<sub>pp</sub>, B<sub>pp</sub>, s)
if (s == 1) /* if submatrix has one element */
   C = A * B; /* multiply elements */
                    /* continue to make recursive calls */
else {
   P0 = mat_mult(A_{pp}, B_{pp}, s);
   P1 = mat_mult(A<sub>bq</sub>, B<sub>qp</sub>, s);
   P2 = mat_mult(A<sub>bp</sub>, B<sub>pq</sub>, s);
   P3 = mat_mult(Apq, Bqq, s);
   P4 = mat_mult(A_{rp}, B_{pp}, s);
   P5 = mat_mult(A<sub>aa</sub>, B<sub>ap</sub>, s);
   P6 = mat_mult(A_{qp}, B_{pq}, s);
   P7 = mat_mult(A_{qq}, B_{qq}, s);
   C<sub>pp</sub> = P0 + P1; /* add submatrix products to */
   C<sub>pq</sub> = P2 + P3; /* form submatrices of final matrix */
   C_{qp} = P4 + P5;
   C_{aa} = P6 + P7;
                         /* return final matrix */
return (C);
```

Mesh Implementations

- Cannon's algorithm
- Fox's algorithm (not in textbook but similar complexity)
- Systolic array

All involve using processor arranged a mesh and shifting elements of the arrays through the mesh. Accumulate the partial sums at each processor.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Mesh Implementations Cannon's Algorithm

Uses a mesh of processors with wraparound connections (a torus) to shift the A elements (or submatrices) left and the B elements (or submatrices) up.

- 1. Initially processor $P_{i,j}$ has elements $a_{i,j}$ and $b_{i,j}$ (0 i < n, 0 k < n).
- 2. Elements are moved from their initial position to an "aligned" position. The complete ith row of A is shifted i places left and the complete jth column of B is shifted j places upward. This has the effect of placing the element a_{i,j+i} and the element b_{i+j,j} in processor P_{i,j}. These elements are a pair of those required in the accumulation of c_{i,j}.

3.Each processor, P_{i,j}, multiplies its elements.

- 4. The ith row of A is shifted one place right, and the jth column of B is shifted one place upward. This has the effect of bringing together the adjacent elements of A and B, which will also be required in the accumulation.
- 5. Each processor, $P_{i,j}$, multiplies the elements brought to it and adds the result to the accumulating sum.
- 6. Step 4 and 5 are repeated until the final result is obtained (n 1 shifts with n rows and n columns of elements).

Movement of A and B elements

Step 2 — Alignment of elements of A and B

Step 4 — One-place shift of elements of A and B

Solving a System of Linear Equations

 $a_{n-1,0}x_0 + a_{n-1,1}x_1 + a_{n-1,2}x_2 \qquad \dots \qquad + a_{n-1,n-1}x_{n-1} = b_{n-1}$

 $\begin{array}{rcl} a_{2,0}x_0 + a_{2,1}x_1 + a_{2,2}x_2 & \dots & + a_{2,n-1}x_{n-1} & = b_2 \\ a_{1,0}x_0 + a_{1,1}x_1 + a_{1,2}x_2 & \dots & + a_{1,n-1}x_{n-1} & = b_1 \\ a_{0,0}x_0 + a_{0,1}x_1 + a_{0,2}x_2 & \dots & + a_{0,n-1}x_{n-1} & = b_0 \end{array}$

which, in matrix form, is

 $\mathbf{A}\mathbf{x} = \mathbf{b}$

Objective is to find values for the unknowns, x_0 , x_1 , ..., x_{n-1} , given values for $a_{0,0}$, $a_{0,1}$, ..., $a_{n-1,n-1}$, and b_0 , ..., b_n .

Solving a System of Linear Equations

Dense matrices

Gaussian Elimination - parallel time complexity $O(n^2)$

Sparse matrices

By iteration - depends upon iteration method and number of iterations but typically O(log n)

- Jacobi iteration
- Gauss-Seidel relaxation (not good for parallelization)
- Red-Black ordering
- Multigrid

Gaussian Elimination

Convert general system of linear equations into triangular system of equations. Then be solved by Back Substitution.

Uses characteristic of linear equations that any row can be replaced by that row added to another row multiplied by a constant.

Starts at the first row and works toward the bottom row. At the *i*th row, each row *j* below the *i*th row is replaced by row $j + (row i) (-a_{j,j}/a_{i,j})$. The constant used for row *j* is $-a_{j,j}/a_{i,j}$. Has the effect of making all the elements in the *i*th column below the *i*th row zero because

$$a_{j,i} = a_{j,i} + a_{i,i} \frac{-a_{j,i}}{a_{i,i}} = 0$$

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved.

Gaussian elimination

Partial Pivoting

If $a_{i,i}$ is zero or close to zero, we will not be able to compute the quantity $-a_{i,i}/a_{i,i}$.

Procedure must be modified into so-called *partial pivoting* by swapping the *i*th row with the row below it that has the largest absolute element in the *i*th column of any of the rows below the *i*th row if there is one. (Reordering equations will not affect the system.)

In the following, we will not consider partial pivoting.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Sequential Code

Without partial pivoting:

```
for (i = 0; i < n-1; i++) /* for each row, except last */
   for (j = i+1; j < n; j++) {/*step thro subsequent rows */
        m = a[j][i]/a[i][i]; /* Compute multiplier */
        for (k = i; k < n; k++)/*last n-i-1 elements of row j*,
            a[j][k] = a[j][k] - a[i][k] * m;
        b[j] = b[j] - b[i] * m;/* modify right side */
    }
</pre>
```

The time complexity is $O(n^3)$.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

slides11-31

Parallel Implementation

Analysis Communication

n - 1 broadcasts performed sequentially. *i*th broadcast contains n - i + 1 elements.

Time complexity of (n^2) (see textbook)

Computation

After row broadcast, each processor P_j beyond broadcast processor P_j will compute its multiplier, and operate upon n - j + 2 elements of its row. Ignoring the computation of the multiplier, there are n - j + 2 multiplications and n - j + 2 subtractions.

Time complexity of (n^2) (see textbook).

Efficiency will be relatively low because all the processors before the processor holding row *i* do not participate in the computation again.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Pipeline implementation of Gaussian elimination

Cyclic-Striped Partitioning

An alternative which equalizes the processor workload:

Iterative Methods

Time complexity of direct method at (N^2) with N processors, is significant.

Time complexity of iteration method depends upon:

- the type of iteration,
- number of iterations
- number of unknowns, and
- required accuracy

but can be less than the direct method especially for a few unknowns i.e a sparse system of linear equations.

Jacobi Iteration

Iteration formula - *i*th equation rearranged to have *i*th unknown on left side:

$$x_{i}^{k} = \frac{1}{a_{i,i}} \begin{bmatrix} b_{i} - a_{i,j} x_{j}^{k-1} \end{bmatrix}$$

Superscript indicates iteration:

$$x_i^k$$
 is kth iteration of x_i , x_j^{k-1} is (k–1)th iteration of x_j .

Example of a Sparse System of Linear Equations

Laplace's Equation

$$\frac{{}^{2}f}{{}^{2}x^{2}} + \frac{{}^{2}f}{{}^{2}y^{2}} = 0$$

Solve for *f* over the two-dimensional x-y space.

For a computer solution, *finite difference* methods are appropriate

Two-dimensional solution space is "discretized" into a large number of solution points.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Finite Difference Method

If distance between points, , made small enough:

$$\frac{\frac{2}{f}}{\frac{2}{x^{2}}} = \frac{1}{2} [f(x + y) - 2f(x, y) + f(x - y)]$$

$$\frac{\frac{2}{f}}{\frac{2}{y^{2}}} = \frac{1}{2} [f(x, y + y) - 2f(x, y) + f(x, y - y)]$$

Substituting into Laplace's equation, we get

$$\frac{1}{2}[f(x + y) + f(x - y) + f(x, y + y) + f(x, y - y) - 4f(x, y)] = 0$$

Rearranging, we get

$$f(x, y) = \frac{[f(x - y) + f(x, y - y) + f(x + y) + f(x, y + y)]}{4}$$

Rewritten as an iterative formula:

$$f^{k}(x, y) = \frac{[f^{k-1}(x - y) + f^{k-1}(x, y - y) + f^{k-1}(x + y) + f^{k-1}(x, y + y)]}{4}$$

$$f^{k}(x, y) - k$$
th iteration, $f^{k-1}(x, y) - (k - 1)$ th iteration.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Natural Order

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved.

Relationship with a General System of Linear Equations

Using natural ordering, *i*th point computed from *i*th equation:

$$x_{i} = \frac{x_{i-n} + x_{i-1} + x_{i+1} + x_{i+n}}{4}$$

or

$$x_{i-n} + x_{i-1} - 4x_i + x_{i+1} + x_{i+n} = 0$$

which is a linear equation with five unknowns (except those with boundary points).

In general form, the *i*th equation becomes:

$$a_{i,i-n}x_{i-n} + a_{i,i-1}x_{i-1} + a_{i,i}x_i + a_{i,i+1}x_{i+1} + a_{i,i+n}x_{i+n} = 0$$

where
$$a_{i,i} = -4$$
, and $a_{i,i-n} = a_{i,i-1} = a_{i,i+1} = a_{i,i+n} = 1$.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Gauss-Seidel Relaxation

Uses some newly computed values to compute other values in that iteration.

Gauss-Seidel Iteration Formula

$$x_{i}^{k} = \frac{1}{a_{i,i}} \left[b_{i} - \frac{i-1}{j=1} a_{i,j} x_{j}^{k} - \frac{N}{j=i+1} a_{i,j} x_{j}^{k-1} \right]$$

where the superscript indicates the iteration.

With natural ordering of unknowns, formula reduces to

$$x_{i=}^{k}(-1/a_{i,i})[a_{i,i-n}x_{i-n}^{k}+a_{i,i-1}x_{i-1}^{k}+a_{i,i+1}x_{i+1}^{k-1}+a_{i,i+n}x_{i+n}^{k-1}]$$

At the *k*th iteration, two of the four values (before the *i*th element) taken from the *k*th iteration and two values (after the *i*th element) taken from the (k-1)th iteration. We have:

$$f^{k}(x, y) = \frac{[f^{k}(x - y) + f^{k}(x, y - y) + f^{k-1}(x + y) + f^{k-1}(x, y + y)]}{4}$$

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved

Red-Black Ordering

First, black points computed. Next, red points computed. Black points computed simultaneously, and red points computed simultaneously.

Red-Black Parallel Code

Higher-Order Difference Methods

More distant points could be used in the computation. The following update formula:

$$f^{k}(x, y) =$$

$$\frac{1}{60} \Big[16f^{k-1}(x - y) + 16f^{k-1}(x, y - y) + 16f^{k-1}(x + y) + 16f^{k-1}(x, y + y) - f^{k-1}(x, y + y) \Big]$$

Nine-point stencil

Overrelaxation

Improved convergence obtained by adding factor $(1 -)x_i$ to Jacobi or Gauss-Seidel formulae. Factor is the *overrelaxation parameter*.

Jacobi overrelaxation formula

$$x_{i}^{k} = \frac{1}{a_{ii}} \begin{bmatrix} b_{i} - a_{ij} x_{i}^{k-1} \end{bmatrix} + (1 - x_{i}^{k-1}) x_{i}^{k-1}$$

where 0 < < 1.

Gauss-Seidel successive overrelaxation

$$x_{i}^{k} = \frac{1}{a_{ii}} \begin{bmatrix} b_{i} - \frac{i-1}{j=1} a_{ij} x_{i}^{k} - \frac{N}{j=i+1} a_{ij} x_{i}^{k-1} \end{bmatrix} + (1 - 1) x_{i}^{k-1}$$

where 0 < 2 If = 1, we obtain the Gauss-Seidel method.

Slides for Parallel Programming Techniques & Applications Using Networked Workstations & Parallel Computers 2nd ed., by B. Wilkinson & M. Allen, 2004 Pearson Education Inc. All rights reserved.

Multigrid Method

First, a coarse grid of points used. With these points, iteration process will start to converge quickly.

At some stage, number of points increased to include points of the coarse grid and extra points between the points of the coarse grid. Initial values of extra points found by interpolation. Computation continues with this finer grid.

Grid can be made finer and finer as computation proceeds, or computation can alternate between fine and coarse grids.

Coarser grids take into account distant effects more quickly and provide a good starting point for the next finer grid.

(Semi) Asynchronous Iteration

As noted early, synchronizing on every iteration will cause significant overhead - best if one can is to synchronize after a number of iterations.
